

REMARKS

As indicated by the Examiner, this application is in condition for allowance except for the requirement of a Substitute Specification. Accordingly, attached is a Substitute Specification. No new matter has been added. It is respectfully submitted that the application is now in condition for allowance.

Based on the foregoing amendments and remarks, it is respectfully submitted that the claims in the present application, as they now stand, patentably distinguish over the references cited and applied by the Examiner and are, therefore, in condition for allowance. A Notice of Allowance is in order, and such favorable action and reconsideration are respectfully requested.

However, if after reviewing the above amendments and remarks, the Examiner has any questions or comments, he is cordially invited to contact the undersigned attorneys.

Respectfully submitted,

JACOBSON HOLMAN, PLLC

## A STACK OF BAGS WITH SLIDEWAY-AND-CURSOR CLOSURES

### Field of the Invention

The invention relates to bags that are reclosable by means of closure strips, and to the manufacture thereof.

### 5 Background of the Invention

Methods are known for manufacturing bags out of ~~plastics~~ plastic material in which each bag opening has two closure strips and a cursor that slides thereon. During manufacture, the cursor is situated at a predetermined distance from the ends of the strips so as to avoid interfering with the heat-sealing and cutting operations that are performed. However, when the bags are placed one on top of another, the cursors pile up against one another, thereby generating a stack whose height is much greater at the cursors than over the remainder of the bags. Thus, storage of the bags is complicated by the volume of such stacks and by their instability. In particular, it is difficult to make up rolls or stacks having a large number of bags.

U.S. Patent No. 5,682,730 discloses a stack of bags having a lower series of successive bags in which said distance has a first constant value such that the cursors are stacked one on top of another close to one end of the strips, and an upper series of successive bags in which said distance has a second constant value, different from the first value, with the cursors of said second series being stacked one on top of another at the other end of the strips. In this way, the two stacks of cursors do not interfere

with each other and both of them occupy almost the same height, thereby greatly reducing the total height of the stack. That disposition is made possible because the bags are flexible. Nevertheless, the height of the stack of bags remains relatively large.

#### Summary of the Invention

An object of the invention is to improve storage of bags, in particular for the purpose of making rolls or stacks of a very large numbers of bags.

According to the invention, this object is achieved by a set of at least three consecutive bags in a succession, each bag having two closure strips and a cursor situated at a respective distance from one end of the strips, the strips and the cursor being identical ~~between~~ for each of the bags, and in which, between the bags in each pair of adjacent bags, the ~~said~~ distances are different.

Thus, a disposition of the cursors is obtained which differs from the above-mentioned known disposition and which makes it possible to store the bags in a volume that is different and more stable, and, for example, in a stack that is of smaller height. For example, the cursors can be relatively offset by half the length of a cursor. Under such circumstances, stacking the bags causes the strips to be twisted slightly, and causes the cursors that lie one on another to be inclined. This reduces the volume of the stack at the cursors.

Preferably, the ~~said~~ distances differ by not less than the size of the cursors parallel to the strips.

In this way, the bags can be stacked one on top of another with the strips being contiguous but without the stacked  
5 cursors interfering with one another, the cursors being disposed next to one another. Under such circumstances, the volume of the set of bags corresponds substantially to that generated by the walls and the strips, and is therefore considerably reduced. As a result, the stack of bags is stable.

10 Advantageously, the ~~said~~ distances on adjacent bags vary in a ~~monotonic~~ constant progression.

It is thus possible to stack a very large number of bags while optimizing the volume available for the cursors without  
15 risking interference, even between cursors of bags that are not consecutive.

Advantageously, the ~~said~~ distances vary by an increment that is constant.

Advantageously, the bags are disposed so that their strips are contiguous.

20 Advantageously, the set constitutes a roll of bags.

Advantageously, the set constitutes a stack of bags.

The invention also provides a method of manufacturing at least three bags each having two closure strips and a cursor, the strips and the cursors being identical between the bags, in which  
25 each cursor is disposed at a respective distance from one end of the strips, and in which the cursors are disposed in such a manner

that the ~~said~~ distances are different between any two successive bags.

The invention also provides ~~an installation a~~  
manufacturing system for manufacturing Bags each including two  
5 closure strips and a cursor, the installation comprising means for  
placing each cursor at a respective distance from one end of the  
strips, in which the means are organized to place the cursors of  
any two successive bags at distances that are different.

#### Brief Description of the Drawings

10 Other characteristics and advantages of the invention  
will appear further on reading the following description of a  
preferred embodiment given by way of non-limiting example. In the  
accompanying drawings:

- Figure 1 is a fragmentary view of a bag in cross-  
15 section through its closure strips;

- Figure 2 is a perspective view showing how the cursors  
of a plurality of bags in a set are positioned;

- Figure 3 is an end view of two bags ~~in~~ from Figure 2;

- Figure 4 is an end view of a stack comprising a large  
20 number of bags; and

- Figure 5 is a diagrammatic view of ~~an installation a~~  
manufacturing system of the invention.

## Detailed Description of the Preferred Embodiments

With reference to Figure 1, the invention applies to identical bags 2 of a type that is known ~~per se~~. The bag 2 of ~~plastics~~ plastic material has two rectangular plane walls 4 placed side by side and bonded together via three of their edges so as to constitute a bag ~~proper~~. The unbonded sides form an opening and receive complementary rectilinear closure strips 6 on their inside faces to constitute a releasable leakproof closure. A cursor 8 is slidably mounted on the strips 6 and is shaped ~~in~~ a manner that is not shown but that is known ~~per se~~ so that sliding of the cursor in one direction causes the strips 6 to be associated with each other so as to close the bag 2, while sliding in the opposite direction separates the strips so as to open the bag.

With reference to Figure 5, in the method of the invention for manufacturing bags, the bags 2 are formed from a contiguous membrane 4 and the strips 6 are applied and bonded to the bags continuously at a station 11, before or after the membrane is cut up into individual bags. When the strips 6 are put into place, they can already carry one cursor 8 for each bag, or else the cursors 8 can be fitted after the strips 6 have been placed on the bags. Manufacture includes a step of heat-sealing the ends 10a, 10b of the strips 6 to each other and of cutting the strips in a station 13, which operation may take place simultaneously with the step of cutting the bags apart from one another.

At some stage during manufacture, after the cursor 8 has been put into place, e.g. while the strips 6 are being cut, a positioning device 15 is programmed to slide the cursor 8 of each bag along the strips and to place it at a predetermined distance  $d_1$ ,  $d_2$  from one of the ends 10a of the strips. This distance  $d_1$ ,  $d_2$  is designed so as to be different for any two successive bags 2 during manufacture. Specifically, and with reference to Figure 3, the difference between  $d_1$  and  $d_2$  is an increment  $\underline{i}$  greater than the length  $\underline{l}$  of the cursor 8 parallel to the strips 6. In addition, for a given series of bags 2, e.g. a series of nine bags as shown in Figure 4, the distance  $\underline{d}$  is caused to vary monotonically, i.e. it decreases only or it increases only (as in this case) on going from one bag to the next in the series. The increment  $\underline{i}$  between bags 2 is constant in this case. Care is preferably taken to ensure that the value of the increment  $\underline{i}$  is only slightly greater than the length  $\underline{l}$  of a cursor 8, and in particular is less than  $2 \times \underline{l}$ , e.g. being equal to  $1.5 \times \underline{l}$  so as to ensure that the largest possible number of bags can be included in the same series before reaching the other end 10b of the strips.

At the end of such manufacture, bags 2 are obtained whose cursors 8 are at respective different above-specified distances  $d_1$ ,  $d_2$ . The bags 2 can thus be rolled up and stacked by causing the respective ends 10a and 10b of the strips 6 to coincide without giving rise to mutual interference between the cursors 8 within a given series of bags, or indeed between successive series of bags, such as the two series of nine bags each shown in Figure 4.
